## Lecture 1: Assessing Classification Performance

Mon 04 Oct 2021 15:01

### 1 Contingency Tables

	Predicted +	Predicted −	
Actual +	5 (TP)	5 (FP)	10 ( $\hat{P}$ )
Actual −	4 (FN)	100 (TN)	104 ( $\hat{N}$ )
	9 (P)	105 (N)	114

#### 1.1 Accuracy

$$\text{acc} = \frac{TP + TN}{P + N} = 92.1\% \quad (1)$$

#### 1.2 Precision

$$\text{prec} = \frac{TP}{\hat{P}} = 50\% \quad (2)$$

#### 1.3 Recall/Sensitivity

$$\text{recall} = \frac{TP}{P} = 55.6\% \quad (3)$$

## 1.4 Examples

- Covid19
  - Recall is more important
  - Want less false negatives. Don't want someone with covid (pos) to think they don't have it (neg).
- Google
  - Precision is more important
  - Want less false positives. Don't want an unwanted (pos) to show up in the search results.

## 1.5 Contingency Venn Diagram

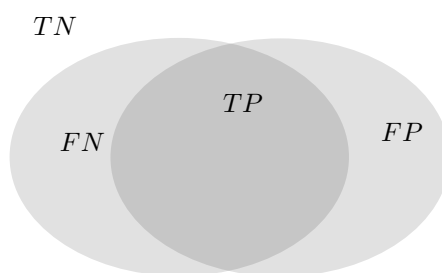

Figure 1: Contingency Venn Diagram

## 2 Coverage Plots

Consider classifiers  $C_1, C_2, C_3$

In a coverage plot, classifiers with the same accuracy are connected by line segments with slope 1. Both  $C_1$  and  $C_3$  dominate  $C_2$ , but the choice of classifier depends on whether we want more true positives (less false negatives), in which case we choose  $C_3$ , or we care less about true positives and want less false positives, in which case we choose  $C_1$ .

So for Covid19, we choose  $C_3$ , and for Google, we choose  $C_1$ ?
